Title: Surveillance Monitoring and Automated Reporting Method for Detecting Data Changes

SPECIFICATION

Statement of Government Interest

The invention was made with Government support under contract No. F04701-93-C-0094 by the Department of the Air Force. The Government has certain rights in the invention.

Field of the Invention

The invention relates to the field of computer monitoring of data changes. More particularly, the present invention relates to surveillance monitoring and automated reporting of detecting changes in monitored data well suited for reporting detected changes in internet websites content data.

111

Background of the Invention

4 Electronic storage of information in computerized
5 databases and file servers has all but replaced the traditional
6 library as a data source of recording knowledge. Modernly, a
7 user provides locating information about the subject matter of
8 interest to be found in an information source. This locating
9 information would include knowledge about the author, title,
10 publication date, or keywords that might appear in a written
11 abstract about the information source. The locating
12 information describes something about the information source,
13 and is commonly referred to as the meta data. Historically,
14 the written word was the primary medium found in books,
15 newspapers, magazines and other periodicals. Modernly, the
16 types of media for recording data have expanded to include
17 magnetic tape, photography, video tape, digital books, computer
18 generated reports, digital audio, digital video, computerized
19 data bases, and internet web pages. Computer based indices have
20 replaced card catalogs as the preferred means for locating
21 various information sources. Most of the newly recorded data is
22 available in electronic form and available via networked
23 computers.

25 Networked computers enable rapid data sharing. The
26 network connection can be made with optical connections, copper
27 wire connections, or can be wireless. The networks can be
28 localized intranets referred to as local area networks.

1 Networks can also include many external computers distributed
2 over a wide physical area as an internet, referred to as wide
3 area networks. To share data information, the networked
4 computers use compatible communications protocols. The most
5 common protocol includes hypertext transport protocol (HTTP),
6 that uses transmission control communication protocol internet
7 protocol (TCP/IP). The largest and most common collection of
8 networked computers is the internet. HTTP is the protocol that
9 is used on the world wide web (WWW) that utilizes the hypertext
10 markup language (HTML) to format and display text, audio, and
11 video data from a data source most often using a WWW browser.
12 The most common method to display information communicated
13 through the WWW is in the form of HTML web pages.

14
15 To view web content data of a particular web page requires
16 a reference to the location of the web page. The web page
17 content data is stored electronically in memory storage devices
18 of a web server. The servers have web domain name addresses to
19 enable retrieval of the information from the local storage. If
20 the desired web content data is on the internet, the web server
21 storing the desired web content data must first be identified.
22 On the internet, computers utilize an internet protocol address
23 (IPA) unique to each web server system. Because numbers are
24 difficult for humans to remember, alias names are used in lieu
25 of the IPA. These alias names are commonly referred to as
26 domain names. A domain name service (DNS) keeps track of which
27 IPAs are represented by the respective domain names. Once a
28 domain name is known, a user can specify the exact directory

1 path to the file of interest containing the desired web content
2 data by specifying the complete domain name and the directories
3 path using a uniform resource locator (URLs) on the web.

4

To locate desired web content data at a particular URL, the user would either be required to specify the exact URL and then manually review the document, or perform a search based on some search criteria. The most common search method employed is through the use of web based search engines. Search engines typically use key words in Boolean combinations to specify search criteria. Boolean combined keyword searches are routinely used by users and provide users with a simple and convenient way of searching for desired web content data. However, Boolean combined keyword searches using search engines often produce millions of URL locations with many nonrelevant web pages pointing to nonrelevant web content data as part of the search result. A search engine match result is also referred to as hit, whether it is relevant or not to the requester. A user often has to manually review many nonrelevant search hits in order to locate relevant search hits. Additionally, typical Boolean combined keyword searches do not provide users with a convenient means to routinely search web pages linked to web page hits. Human review of data is most effective at determining if the source of information is appropriate for required needs, but humans often lack time to perform recurring searches for desired data. While a one time search may be executed by a user, users often have to disadvantageously repeat the identical search process, for

1 example, on a daily basis, in order to monitor changes in web
2 content data. Web based search engines do not provide a means
3 to perform automated routine searches based upon user defined
4 search criteria. These and other disadvantages are solved or
5 reduced using the invention.

28 ///

Summary of the Invention

An object of the invention is to provide a method for routinely searching over a network for changes in data content.

Another object of the invention is to provide a method for routinely searching data sources over a network for changes in data content within defined search criteria.

Yet another object of the invention is to provide a method for routine notification of changes in data content of networked data sources having data content within defined search criteria.

Still another object of the invention is to provide a method for routine notification of changes in data content of data sources connected over a network.

A further object of the invention is to provide a method for routine identification of changes in data content of networked data sources identified by search criteria and having data content also identified by the search criteria.

Yet a further object of the invention is to provide a method for routine identification of linked data sources having data content within defined search criteria.

1 still a further object of the invention is provide a
2 method for routine notification of changes in data content of
3 linked data sources having changed data content within defined
4 search criteria.

5
6 The invention is directed to a method for monitoring
7 networked data sources for changes in data content within
8 defined search criteria and provides users with notification of
9 those changes. The invention is applicable to both web based
10 services and networked systems for providing computer program
11 processes that search for changes in content data. The searches
12 include conventional Boolean combined keyword searches. During
13 web based monitoring, the method monitors changes data of user
14 specified data sources that match the search criteria. The
15 data sources can be web servers identified by uniform resource
16 locators (URLs). The content data can be web content data also
17 identified by the URLs. As a stand alone process executed on a
18 networked computer of a user, the method monitors other network
19 data sources, such as other networked computers, for changes in
20 the data content of the search defined data sources. For web
21 based services, users may be given an account where the users
22 specify a list of information sources, some of which may be in
23 the form of web pages identified by the (URLs) to be monitored
24 and specify associated keywords, or other more complex
25 criteria, that are of a particular interest to the users. The
26 method is well suited for website searches. A URL is used to
27 specify a website with the URL having a http:// scheme, and
28 having a domain name for locating the website. The content data

1 sought at the website can be identified by the path extension
2 of the URL. In the general case of any networked system, a
3 uniform resource identifier could be used to identify the data
4 source, and extensions for identifying the sought after content
5 data.

6
7 In the case of web monitoring, a user interface to the web
8 is the user web browser that provides the URLs pointing to
9 websites and web content data to be searched and monitored.

10 The user selects how often each specified URL, or other
11 networked data source, is to be monitored for changes. The user
12 may also select the methods of detected change notification
13 such as electronic mail, personal digital assistant, pager, or
14 a near real time graphical status display. The user can
15 specify a crawling depth of intradomain hyperlinks that the
16 service will search for occurrence of keywords and selection
17 criteria. The invention preferably uses a web server with
18 interfaces to a database, software programs, common gateway
19 interfaces, and java programs having servlets with a java
20 server. For the stand alone software process, the web based
21 service functions are implemented on a user computer. In the
22 broad form of the invention, the method monitors any networked
23 data source and networked content data in databases and file
24 systems, as well as monitoring websites storing web content
25 data.

26
27 In the preferred form, the method provides a web based
28 service using a dedicated web server that monitors changes in

1 user specified website content data. The method is preferably
2 implemented using the world wide web with communications over
3 the internet. Users may be given an account number for tracking
4 user searches. The users may specify a list of web pages by
5 respective uniform resource locators (URLs) of the web pages to
6 be monitored with associated keywords of interest for each URL.
7 The user interface to the monitoring web server is the user web
8 browser that points to the URL of a monitoring web server.
9 After login into the monitoring web server, the user can then
10 provide the search criteria and the frequency of the searches
11 for each specified URL that is then checked for sampled for
12 changes. The detected change notification can be by way of
13 electronic mail, pager, or a near real-time graphical status
14 display. The user can specify the crawling depth of
15 intradomain hyperlinks that will be searched for occurrence of
16 the specified keywords. The method preferably uses a web
17 server such as an apache web server that interfaces to a
18 database while executing C programs, common gateway interfaces
19 and java programs.

20
21 The method provides automatic recurring notification of
22 search result for any user that desires to stay as current as
23 possible of changing data. Web tools can be used to
24 repetitively locate networked content data with an ability to
25 continuously monitor information sources for updates, or
26 changes, in the content data of only pertinent information
27 within the specified search criteria. The method monitor
28

1 changes of the web content data that are of particular interest
2 to the user on a recurring basis specified by the user.

3

4 The method preferably provides a service website to the
5 user to allow the user to select URLs and corresponding
6 keywords for each URL, the crawling depth to which links will
7 be followed for keyword searching, the frequency of checking
8 for each URL expressed in minutes, hours, or days, the
9 electronic mail, pager, or personal digital assistant addresses
10 to which notification reports will be sent, the category to
11 which the URL will be assigned, and the keyword Boolean
12 expression that will be used to search the web pages. The
13 Boolean expression allows keywords to be joined with AND and OR
14 operators. Once the URL and its parameters are defined, the
15 user then can launch or terminate the search and detection
16 process for each specified URL through the internet.

17

18 The search and detection software is implemented as a
19 search daemon that runs as an independent background process on
20 the host machine that is preferably a web server. As soon as a
21 search daemon is launched, the search daemon follows a
22 predetermined search procedure. A network connection is
23 established to the user specified URL that is to be monitored.
24 A web request is sent over the internet to download the HTML
25 from the URL. All the characters sent in response to the URL
26 request are saved in a file. In addition, a second text only
27 file is created that contains the formatted version of the text
28 without HTML tags. To create this file, while the characters

1 are being received from the data source, any text that is part
2 of an HTML tag is not written to the text only file. All other
3 text characters are written to the file. Thus, after all the
4 HTML data is received for the URL, the text only file contains
5 all the text from the URL minus the HTML tags. During the HTML
6 acquisition, a list of all URL links that appear in the web
7 page is created for crawling through linked pages to the
8 specified crawling depth for determining if the linked pages
9 also match the specified search criteria.

10

11 Changes are detected based on a comparison of the previous
12 text data only version of the web page stored in the database
13 with the newly downloaded text only version of the page, both
14 with duplicative white spaces firstly removed. The new
15 formatted text is compared to the formatted text of the
16 previous version for determining changes in the number of
17 keyword hits matching the Boolean search criteria. If the
18 current and previous text version do not match then further
19 comparison is required in order to avoid reporting of trivial
20 changes that the user would not be interested in. The keyword
21 counts for the new page are determined. If any one of the
22 keyword counts for the new page differs from the corresponding
23 keyword count for the previous version, then a change is
24 declared between the current and previous text only versions.
25 After the initial comparison between the previous version in
26 the database and the new current version is done, the previous
27 version of the page in the database is replaced by the
28 formatted text of the new current version. In this manner,

1 relevant sought after changes are detected. The change
2 detection is repeated as often as the specified search
3 frequency. After each detection of a change in the keyword
4 counts, the user is notified. In this manner, the monitoring
5 method continually searches the content data for changes with
6 automatic reporting to the user. These and other advantages
7 will become more apparent from the following detailed
8 description of the preferred embodiment.

Brief Description of the Drawings

Figure 1 is a block diagram of a monitored distributed network.

Figure 2 is a block diagram of a network connected monitoring and reporting system.

Figure 3 lists a top level portion of a surveillance daemon.

Figure 4A lists a pseudocode for an HTTP client data retrieval portion of a surveillance daemon subroutine.

Figure 4B lists a pseudocode for a change detection portion of the surveillance daemon subroutine.

9 Figure 4C lists a pseudocode for a recursion portion of
0 the surveillance daemon subroutine.

Figure 5 lists a pseudocode for a change detection subroutine.

///

Detailed Description of the Preferred Embodiment

An embodiment of the invention is described with reference to the figures using reference designations as shown in the figures. Referring to Figures 1 and 2, a monitoring distributive network 10, that is preferably the internet, provides interconnection between a surveillance monitoring and automated reporting system 12 simply also referred to as the monitoring system, and plurality of A, B, and C user systems 14a, 14b, and 14c respectively, collectively simply also referred to as users, and a plurality of distributed networked A, B, and C monitored computer systems, 16a, 16b, 16c respectively, and collectively simply also referred to as monitored systems. The networked distributed computer systems 16a, 16b and 16c are preferably websites, but may generally be file systems, databases, and/or local file systems connected to the network 10. The monitored systems 16a, 16b, and 16c are monitored by the monitoring system 12. The user computers 14a, 14b, and 14c connect to the monitoring system 12 and the monitored systems 16a, 16b and 16c through the network 10. The user systems 14a, 14b, and 14c respectively include an A browser 18a, a B browser 18b, and a C Browser 18c, with respective data storage 20a, 20b, and 20c that are typically local disk storage devices of user systems 14a, 14b, and 14c.

27 The monitored distributed network 10 can be a network of
28 varying configurations, and can be, for example a private local

1 area network, a wide area network, or a public network, such as
2 the internet. The user systems 14a, 14b, and 14c can be
3 workstations, personal computers, or larger mainframe computer
4 systems. Each user computer 14a, 14b, and 14c typically
5 includes one or more processors, memories, and input/output
6 devices, all well known but not shown. The browsers 18a, 18b,
7 and 18c are communication interfaces to the network 10 when the
8 monitoring system 12 is particularly adapted for website
9 communications for monitoring websites that may be the
10 monitored web server systems 16a, 16b and 16b, though other
11 types of communication interfaces and information systems may
12 be used. The browser 18a, 18b, and 18c are preferably
13 particularly programmed for searching, sending and receiving
14 web content data for websites of the web servers 16a, 16b and
15 16c located by internet protocol addresses (IPAs) on the
16 internet. The network 10 allows interconnection to a vast array
17 of connected computer systems. The monitored systems 16a, 16b,
18 and 16c are typically information storage systems but are
19 preferably website servers having respective uniform resource
20 locators (URLs) and respectively storing URL identified web
21 content data over the world wide web (WWW). The user systems
22 14a, 14b, and 14c access the web based monitoring service of
23 the monitoring system 12 preferably using the web browsers 18a,
24 18b, and 18c. Although the monitoring system 12 generally
25 focuses on monitoring information systems, such systems are
26 preferably WWW website server systems. However, the monitoring
27 system 12 can also be used for monitoring information through
28 other wide or local area networks, or information stored in any

1 distal computer system using specific networking communications
2 protocols when communicating through the network 10.

3

4 Referring to all of the Figures, the monitoring system 12
5 is preferably a website server computer system for
6 communicating over the internet when the network 10 is the
7 internet and when the monitored information systems 16a, 16b,
8 and 16c are website servers storing URL specific web content
9 data. In the preferred form, the monitoring system 12 is a web
10 based server system including a front end web server 30 for
11 communicating over the internet network 10 using URLs for
12 defining web content data and IPAs for defining website
13 internet network address locations. The monitoring system can
14 launch and concurrently execute a plurality of surveillance
15 daemons, such as surveillance daemons 32a, 32b, and 32c
16 interfacing with a database manager 34 managing a relational
17 database 36. The top level pseudocode for the surveillance
18 daemon is listed in Figure 3. Preferably, each of the
19 surveillance daemon 32a, 32b and 32c concurrently communicate
20 with a respective notification daemon 38a, 38b and 38c. Each
21 pair of surveillance daemon and notification daemon
22 respectively operates in combination to respond to user
23 monitoring requests and provide notification of the monitoring
24 results. User system 14a, 14b, and 14c, using respective
25 browser 18a, 18b, and 18c provide the monitoring system 12 with
26 respective search criteria, in response to which, the
27 monitoring system 12 would invoke respective surveillance
28

1 daemons 32a, 32b, and 32c, and respective notification daemons
2 38a, 38b, and 38c during the monitoring process.

3
4 The monitoring system 12 preferably includes the HTTP web
5 server 30, the database manager 34, the relational database 36,
6 and one or more active surveillance daemons 32a, 32b and 32c,
7 and one or more respective notification daemons 38a, 38b and
8 38c, each particularly configured for web communication using
9 URLs and IPAs over the internet network 10. The notification
10 daemons can include sending notification of changes in web
11 content data through electronic mail, preferably through the
12 internet, but may also include communication through wireless
13 devices including personal digital assistants, pagers and cell
14 phones, and a near real-time graphical display of information
15 source detected changes. The automated web browsers 42 of the
16 surveillance daemons 32a, 32b, and 32c, function to
17 respectively communicate with the monitored web information
18 systems 16a, 16b, and 16c, during searching as the change
19 detection module 40 of the respective surveillance daemon 32a,
20 32b and 32c function to detect change in the specified web
21 content data. The surveillance daemon includes change detection
22 and searching algorithms using a website monitoring code that
23 is implemented as a software module. The notification daemons
24 38a, 38b, and 38c function to respectively communicate with the
25 user systems 14a, 14b, and 14c during notification of
26 monitoring results. Each of the surveillance daemons 32a, 32b
27 and 32c are invoked by launching the top level pseudocode of
28 Figure 3 that can preferably launch respective surveillance

1 daemon subroutines of the respective pseudocode listed in
2 Figures 4A, 4B, and 4C. The surveillance daemons 32a, 32b and
3 32c include respective HTTP client modules 42 when executing
4 the HTTP client portion of Figure 4A of the surveillance
5 subroutine, and have respective change detection modules 40
6 when executing the change detection portion of Figure 4B of the
7 subroutine that in turn uses the recursion portion of Figure 4C
8 and the change detection subroutine of Figure 5. The HTTP
9 client 42 can be implemented as an automated web browser. The
10 change detection module 40 and the HTTP client module 42
11 operate in combination during monitoring with the HTTP client
12 module fetching web pages within search criteria and with the
13 change detection module determining changes in the fetched web
14 pages.

15
16 The surveillance daemon of Figure 3 is implemented as a
17 top level pseudocode algorithm for performing basic monitoring
18 functions. Each set of user specified search criteria is
19 associated with an invoked surveillance daemon 32a 32b, or 32c
20 at line 101. Whenever the user 14a, 14b or 14c invokes a
21 search on the search criteria, a START/STOP flag in the
22 database 36 for that search criteria is set to TRUE indicating
23 that the surveillance daemon 32 has been launched for those
24 search criteria in the monitoring system 12. A RUN flag in the
25 database 36 indicates whether the surveillance daemon 32 for
26 the search criteria is currently running. When the
27 surveillance daemon is started at line 100 and begins execution
28 at line 103, the surveillance daemon first sets at line 105 the

1 RUN flag to be TRUE. The surveillance daemon 32 then creates a
2 global list V at line 106 to store links that have been visited
3 during link traversal. At line 107 the surveillance daemon sets
4 a GO flag and then enters a search loop at line 108 and
5 extending to line 121 and continues to execute the search loop
6 until the surveillance daemon detects that the START/STOP flag
7 has been set to FALSE. Inside the search loop between lines
8 108 and 121, the surveillance daemon retrieves user specified
9 information at line 110 from the database 36 specifying a top
10 level URL, a time duration between searches, and a crawling
11 depth. Next, the surveillance daemon calls at line 112 the
12 surveillance daemon SearchURL subroutine of Figures 4A, 4B and
13 4C, with the top level URL, the crawling depth information, and
14 the current crawling level being passed as arguments to the
15 surveillance daemon SearchURL subroutine.

16
17 During surveillance daemon subroutine calls, links of the
18 top level URL are searched during link crawling and process
19 control of the subroutine terminates and process control
20 returns to surveillance daemon at line 113. At line 113, the
21 surveillance daemon checks the value of the START/STOP flag.
22 If the START/STOP flag is still TRUE at line 115, then the
23 surveillance daemon 32 sleeps at line 117 for the time duration
24 specified by the user as the interval between searches. Upon
25 waking at lines 118 and 119, the surveillance daemon 32 checks
26 the value of the START/STOP flag again at line 108. If the
27 START/STOP flag is still true at line 108, then the search loop
28 starting at line 109 is executed again. This search loop is

1 repetitively executed at a frequency determined by the time
2 duration intervals that allow the surveillance daemon to run
3 continuously, checking the top level URL for changes at the
4 frequency specified by the user specified time duration. If
5 the START/STOP flag is false at line 108 when the surveillance
6 daemon awakes, then the run flag is set to FALSE at line 122
7 and the surveillance daemon terminates execution at line 124.

8

9 The surveillance daemon 32 of top level pseudocode of
10 Figure 3 calls the HTTP portion of the surveillance daemon
11 subroutine at line 112 to start execution at line 128 of the
12 HTTP client portion. At line 128, the HTTP client portion is
13 referenced as a subroutine SearchURL and begins at line 130. At
14 line 132 a link list L is created to store all HTML links that
15 are contained in a page specified by the top level URL and
16 linked URLs. There are two files that are created during the
17 processing of the content data of a top level or linked URL. A
18 first HTML file stored in the monitoring system 12 receives all
19 of the characters that are returned over the network through a
20 network socket of the monitored website specified by the top
21 level or linked URL. The network socket connection is created
22 at line 135 to the website corresponding to the top level URL
23 or linked URL to receive the HTML web content data in a buffer
24 that forwards one character at a time through a character
25 retrieval loop of lines 139 through 157 of the HTTP client
26 portion to the HTML file stored in the monitoring system 12.
27 The entire HTML file is transferred at line 141 from the buffer
28 during a retrieval loop line 137 through line 158. A second

1 formatted text file receives the text returned from the top
2 level or linked URL with the HTML tags stripped out between
3 lines 142 through 156. The formatted text (FT) file is created
4 one character at a time at lines 154 and 155. Each HTML web
5 content data character is transferred through the buffer to the
6 HTML file unconditionally at line 141. If the character is not
7 part of an HTML tag at line 142, then the character is also
8 written to the formatted text file at line 155. In order to
9 know whether a given character is within an HTML tag, a check
10 at line 142 is done on each character to see if the character
11 marks the beginning of a HTML tag. If the character marks the
12 beginning of an HTML tag, then web content data characters are
13 read from the buffer until the end of the HTML tag is found.
14 These tag characters are written to the HTML file at line 146
15 but not to the formatted text file. The HTML tag characters
16 are then examined at line 147 to determine if the HTML tag is a
17 link to a linked URL. If the HTML tag characters are a link to
18 a linked URL, then the linked URL is extracted from the HTML
19 tag characters and added to the end of the link list L at line
20 149. If the HTML tag characters are not a link, then the HTML
21 tag characters form an HTML tag and are ignored. The process of
22 reading and examining HTML web content data characters is
23 continued by the loop lines 139 through 157 until all of the
24 web content characters are processed for the URL, at which time
25 the buffer is empty and the network socket is closed. The HTML
26 file is retained as a complete record in the monitoring system
27 12 as an exact HTML copy of the web content data for the URL.
28

1 The formatted text file is used for all further processing by
2 the surveillance daemon.

3
4 The formatted text file is processed in the monitoring
5 system one character at a time and stored as a single large
6 formatted string. During formatted text file processing, the
7 formatted text is formatted to eliminate excess white space at
8 lines 160 and 161. Each character that is not a white space
9 character is appended to the end of the formatted text string.
10 Each contiguous segment of white spaces in the formatted text
11 file is converted to a single blank character and then appended
12 in order at line 160 to formatted text string FS.

13
14 After creating the resulting formatted text string of the
15 pseudocode of Figure 4A, a change detection algorithm of Figure
16 4B is called to determine if the formatted text string has
17 changed from a previously stored formatted text string. The
18 change detection algorithm of Figure 4B preferably only checks
19 for change detection respecting the web content data of top
20 level URLs at line 163. If the current formatted text string is
21 generated from a top level URL, then a change detection section
22 of lines 166 through 183 is executed. Firstly, the change
23 detection section calls at line 166 the change detection
24 subroutine of Figure 5. The change detection subroutine of
25 Figure 5 checks to determine if the formatted text string has
26 changed since the last search of that top level URL, and if so,
27 produces an updated keyword hit count and returns back to the
28 change detection portion at line 170. The change detection

1 portion examines the true or false result of the change
2 detection subroutine at line 170 to determine if the change
3 detection subroutine has determined if there has been a change
4 since the last time that the top level URL web content data
5 formatted text string was formatted and updated in the database
6 36.

7
8 The change detection subroutine of Figure 5 returns the
9 result of the comparison of the previous and current formatted
10 text strings back to the calling subroutine SearchURL of
11 Figures 4A, 4B and 4C. The flag TrueChange is set to TRUE if a
12 significant change was detected at line 172, and if no change
13 was detected, the flag TrueChange is set to FALSE. If a change
14 was detected, then the new keyword counts that were generated
15 by the change detection algorithm are added to the database,
16 replacing the counts from the old previous version P. Then an
17 ASCII activity report is generated at line 175. This ASCII
18 activity report is added to the database at line 176 and sent
19 to the user at line 177 through the notification method that
20 the user has specified to be through either electronic mail,
21 pager, or personal digital assistant. When a true change
22 between the new version and previous version is detected, the
23 results are presented to the user in two different formats to
24 enable change and keyword hit notification. First, an
25 electronic message is created and sent to one or more of the
26 user's electronic mail address, pager, or personal digital
27 assistant depending on what reporting options were chosen.
28 This message is an activity report. The message should indicate

1 that a hit has occurred while specifying URLs, keywords, and
2 the number of respective keyword hits, with an abstract that
3 includes, for example, the ten words before and ten words after
4 each keyword hit. The notification may further request the user
5 to log in to the monitoring system 12 for more search result
6 information. All keyword counts should be shown. A limited
7 number of abstracts from the text may be shown as well. The
8 abstracts may be chosen based on the keywords with the highest
9 frequency of occurrence.

10
11 The recursive portion of Figure 4C of the SearchURL
12 subroutine is executed for each of the URLs in the link list L.
13 The change detection portion jumps to line 186 when the link U1
14 is not the top level URL, that is, when the level is greater
15 than zero, when processing each U1 link from the link list L.
16 The change detection subroutine of Figure 5 is executed once
17 for the top level URL at line 166. The top level keyword counts
18 for the top level URL and the reporting to the user between
19 lines 170 and 184 is also executed once when processing the top
20 level URL. The processing of the U1 links in list L between
21 lines 188 and 195 and the recursive portion of Figure 4C is
22 executed for each of the U1 links in the link list L. During
23 each execution of the SearchURL subroutine for each of the U1
24 links, the SearchURL subroutine determines the number of N
25 occurrences of each of the W keywords in each of U1 links of
26 the link list L. The N occurrences of the W keywords are found
27 for each link U1 in the link list L during each recursive call
28 to the SearchURL subroutine that includes the recursive

1 portion. The change detection portion between lines 188 and 195
2 determines the N occurrences of each of the W keywords for each
3 link U1 in the link list L. The W keywords are extracted from
4 the database at line 188. The W keywords are those associated
5 with the top level URL. The N number of occurrences of each of
6 the W keywords in the U1 links are determined and added to the
7 total count T at lines 190 through 194. For each of the W
8 keywords at line 190, the N occurrences of the keyword is
9 counted at line 192 to accumulate the total T keyword count for
10 all of the W keywords for each of the U1 links. The N
11 occurrences for each of the W keywords is added to the total
12 number of keywords hits T at line 193. When the keyword
13 counting is complete, T is the total number of occurrences of
14 all of the W keywords in the respective U1 link being
15 processed. The total keyword count T, the keyword occurrence
16 count N for each of the W keywords, and the crawled-to URL,
17 that is the current U1 link, are updated in the database at
18 line 195. The U1 link and the respective T total count for all
19 of the W keywords contained in the U1 link are inserted into
20 the database for later display and reporting.

21
22
23 The recursion algorithm of Figure 4C is a link traversal
24 algorithm. If flag TrueChange is TRUE at line 200, then the
25 SearchURL subroutine will attempt to traverse any links that
26 are in the page specified by the URL. All of these links are
27 contained in the previously created list L at line 149. A
28 recursive loop at line 203 examines each link in list L

1 starting at the beginning of the list and first determines if
2 the list L is empty. If the link list is not empty, then the
3 first link U1 is removed from the list at line 205. A check is
4 done at line 206 to determine if the current link level is
5 greater than or equal to the maximum crawling depth for link
6 traversal that was specified by the user. When processing the
7 top level URL, the link level is zero. If link level is less
8 than the maximum crawling depth at line 206, then the link is
9 checked to see if the link has already been processed by
10 checking if the link U1 is in the list V of visited links at
11 line 209. If link U1 is not in the list V, then the domain of
12 U1 is determined at lines 212 and 213. If the domain of link
13 U1 matches the domain of the original top level URL at line
14 212, then the link U1 is eligible to be searched for keywords
15 and for other links, and in so doing, the link U1 will become
16 traversed. Only links with the same domain are searched in
17 order to avoid unacceptably large link search trees. The link
18 U1 is added to list V at line 215 to show that the link has
19 been processed. A recursive call to the SearchURL subroutine
20 is performed at line 219 with arguments of link U1 as the URL,
21 crawling depth, and link level plus one because the processing
22 is progressing down one level in link traversal. The recursion
23 portion of the SearchURL subroutine recursively calls the
24 SearchURL subroutine for each of the URLs in the link list L.
25

26 The recursive portion of the SearchURL subroutine of
27 Figure 4C, is executed at line 200 when the link level is
28 greater than zero indicating a U1 linked URL is being

1 processed. At this point the link list L contains all the
2 links contained within the page specified by URL U1. The URL,
3 which may be the top level URL or a linked URL, is examined at
4 line 163. When the URL is a linked URL, processing jumps to
5 lines 188 through 195 to count the keywords in the linked URL.
6 During a first execution of the SearchURL subroutine, when
7 processing the top level URL, change detection is performed and
8 keywords are counted between lines 166 and 183. After
9 processing the top level URL, the recursion portion first
10 determines that there has been a true keyword change or that
11 processing is not at the top level URL of zero so that the
12 links can be processed at line 200. When the link list L is not
13 empty, and the first URL of the link list L is removed at line
14 205, the removed U1 link is then processed. If the crawling
15 depth of the removed link has a depth less than the user
16 specified depth at line 206, the removed link is compared to
17 the domain of the top level URL at lines 212 and 213. If the
18 current depth level of the removed link is less than the user
19 specified depth, and the removed URL has the same domain as the
20 top level URL, and the URL is not in the visited list V, then
21 another recursive call to SearchURL is initiated for processing
22 the link in the link list L. This recursive process continues
23 in the loop between lines 203 to 223 until all the links in the
24 link list L have been checked. During each loop between lines
25 203 and 223, the SearchURL subroutine is recursively called at
26 line 219 to count the keywords between lines 188 and 195. When
27 any link in the link list L generates a set of embedded links,
28 the embedded links are added to the link list when executing

1 the HTTP client data retrieval portion of the SearchURL
2 subroutine of Figure 4A. All of the links in the link list L
3 are processed by a recursive call of the SearchURL subroutine
4 so that the SearchURL subroutine crawls through each of the
5 links to the specified crawling depth. When the crawl level of
6 the removed link becomes equal to or greater than the specified
7 crawling depth, then the recursive call of the SearchURL
8 subroutine will not be executed. The recursive call allows
9 link traversal to stop when the SearchURL subroutine has
10 reached the user specified crawling depth. After all links in
11 link list L have been processed, the recursive call to
12 SearchURL terminates at line 226 and control is returned to
13 line 113 of the surveillance daemon of Figure 3.

14

15 During execution of the change detection portion of the
16 SearchURL subroutine, the change detection subroutine of Figure
17 5 is called at line 166 when processing the top level URL to
18 jump to line 301 of the change detection subroutine. The change
19 detection subroutine determines true changes in the top level
20 URL. The SearchURL subroutine is repeatedly called at time
21 intervals at line 112 to begin initial processing of the URL at
22 the regular intervals of sleep at line 117. During each initial
23 processing of the top level URL, the change detection portion
24 at line 166 jumps to the change detection subroutine at line
25 301 to begin at line 304 determining when there has been a true
26 change in the top level URL. During repeated monitoring of the
27 top level URL, the text of the URL may be repeatedly updated in
28 the database. At the beginning of each execution of the change

1 detection subroutine, the previous version of the text for the
2 top level URL has been stored in the database as P string.
3 This previously stored P string is retrieved at lines 306 and
4 307 from the database. The change detection subroutine then
5 makes direct comparison between the P string and the new
6 formatted text string FS at lines 308. If there is at least one
7 character that is different between the P string and FS string,
8 then there may be potential significant difference between the
9 two text versions that must then be processed to determine if
10 there has been a true change. The FS string replaces the P
11 string in the database at line 310 to keep the database current
12 with the text of the top level URL. To determine if there has
13 been a true change, the Boolean keyword expression (Exp) that
14 had been previously specified by the user for the top level URL
15 is retrieved from the database at lines 311 to 312. The FS
16 string is searched at lines 313 for matches with Exp
17 expression. If the expression Exp is found in FS string at line
18 314 indicating that the W keywords exist in FS in compliance
19 with the Exp Boolean expression, then the W keywords associated
20 with the URL are retrieved from the database at line 316 and
21 then, for each of the W keywords at line 317 a keyword count is
22 executed at line 319 for determining the number of occurrences
23 of each of the W keywords.

24

25 The keyword counts for the previous version P string are
26 retrieved from the database at line 321. If at least one
27 keyword count for FS is different from the corresponding
28 keyword count for the same keyword in the P string at line 324,

1 then the change detection subroutine determines at line 328
2 that a significant difference exists between the previous P
3 string and the new formatted FS string of the text and a true
4 change is declared at line 328. In any other case, between
5 lines 330 and 341, no change is declared. The change detection
6 subroutine ends at line 344 and returns to the change detection
7 portion where the true change is examined at line 170 and the
8 TrueChange flag is either set to TRUE at line 172 or FALSE at
9 line 182. In this manner, the change detection subroutine
10 determines true changes since the last time that the top level
11 URL was visited. After all processing for a particular top
12 level URL is completed, including traversal of all links
13 contained in the top level and lower level pages, the
14 surveillance daemon then sleeps for a sleep period of time
15 equal to the frequency interval that was specified by the user.
16 If the user has chosen to terminate the processing of the
17 surveillance daemon, then the surveillance daemon exits at line
18 124.

19

20 As may now be apparent, the surveillance daemon is used to
21 repeatedly monitor user specified URLs at repeated user
22 specified sleep intervals to a user specified link crawling
23 depth searching for matches and changes in the matches to user
24 specified keywords and keyword Boolean expressions. In the
25 event of a change, the notification daemon provides rapid
26 electronic notification with transmitted data so that the user
27 can view the results. After URL monitoring notification, the
28 user can preferably view details of the search results from a

1 service at a website. An HTML page displaying a format similar
2 to the electronic version can be made available to the user.
3 Preferably a page is provided to view the total keyword counts
4 obtained from searching URL links that were followed from the
5 top level or subsequent lower level pages during link traversal
6 crawling. The near real time graphical status display may
7 consist of two pop up windows that show the user two
8 dimensional or three dimensional graphs that are repeatedly
9 updated, for example, every sixty seconds. The graph may show
10 the number of hits per category and the age of the data. Bars
11 of the graph may be color coded to show aging. The combination
12 of size and color may show the user the activity and the age of
13 the oldest data for that category. Each bar in the graph may
14 be clicked to bring up a new window showing either the
15 category, one day, or one month results depending on which part
16 of the graph is selected. A three dimensional display window
17 may show the user the breakdown of hits and separates the hits
18 into multiple day intervals. As may be apparent, there are many
19 possible formats by which to display search results to the
20 users.

24
25
26
27
28

1 The present invention is directed to monitoring data over
2 a network, and preferably monitors web content data over the
3 world wide web through internet communications using a
4 programmed server that receives user specified search criteria
5 including keywords, Boolean expressions, crawling depths, and
6 sleep periods between searches, and preferably provides the
7 user with automated notifications and website displays of the
8 search results. The monitoring system provides the users with
9 notification of changes in the web content data of selected
10 websites. Those skilled in the art can make enhancements,
11 improvements, and modifications to the invention, and these
12 enhancements, improvements, and modifications may nonetheless
13 fall within the spirit and scope of the following claims.
